STUDIES RELATED TO WILDERNESS

Bureau of Land Management Wilderness Study Areas

The Federal Land Policy and Management Act (Public Law 94-579, October 21, 1976) requires the U.S. Geological Survey and the U.S. Bureau of Mines to conduct mineral surveys on certain areas to determine their mineral values, if any. Results must be made available to the public and be submitted to the President and the Congress. This report presents the results of a geochemical survey of the Nopah Mountain and Resting Spring Wilderness Study Areas, California Desert Conservation Area, Inyo County, California.

INTRODUCTION

In November and December 1982 we conducted a reconnaissance geochemical survey of the Nopah Mountain Wilderness Study Area (WSA), Inyo County, California.

The Nopah Mountain WSA comprises about 147 mi^2 (380 km^2) in the southwest corner of Inyo County, California. Access to the vicinity of the study area is provided by foot and 4-wheel-drive vehicle. Access to the Nopah Mountain WSA is provided by county road.

The study area occupies the northern portion of the Nopah Range and the southern portion of the Resting Spring Range. The Nopah Range and Resting Spring Range are divided into major structural units containing pre-Cenozoic rocks separated by thrust faults (Burchfiel and others, 1981). Several Cenozoic rock units are exposed in the study area, but only in the southern portion of the Resting Spring Range does a Cenozoic rock unit, a Tertiary-welded tuff, have a large area extent compared to pre-Cenozoic rocks. Burchfiel and others (1982) describe pre-Cenozoic rocks in the northern Resting Spring Range and northern Nopah Range.

The topographic relief in the study area is about 4626 ft (1410 m), with a maximum elevation of 6394 ft (1949 m). Both the Resting Spring Range and the Nopah Range are incised by steep-walled, intermittent streams and bound by coalescing alluvial fans. The climate is arid to semiarid.

In March 1982 we conducted a reconnaissance geochemical survey of the Resting Spring Wilderness Study Area (WSA), Inyo County, California.

The Resting Spring Wilderness Study Area comprises about 118 mi^2 (305 km^2) in the southwest corner of Inyo County, California. Access to the vicinity of the study area is provided by helicopter. Access to the Resting Spring WSA is provided by county road.

The study area occupies the northern portion of the Resting Spring Range, which is divided into four major structural units. Each unit contains pre-Cenozoic rocks separated by thrust faults (Burchfiel and others, 1981). A large number of Cenozoic rock units are exposed in the study area, but compared to the pre-Cenozoic rocks, are of small area extent. Pre-Cenozoic rock units are described in detail by Burchfiel and others (1982).

The topographic relief in the study area is about 3070 ft (936 m), with a maximum elevation of 5073 ft (1546 m). The Resting Spring Range is incised by steep-walled, intermittent streams and bound by coalescing alluvial fans. The climate is arid to semiarid. A more detailed discussion of the geology and geochemistry of both the Nopah Mountain Wilderness Study Area (WSA) and the Resting Spring WSA will be published elsewhere.

METHODS OF STUDY

Sample Collection

We collected samples at 112 sites (Plate 1) in the Nopah Mountain WSA. At nearly all of those sites, we collected both a stream-sediment sample and a heavy-mineral concentrate. In order to geochemically characterize known mineralized areas composite grab samples of rocks were collected from a prospect pit (NP445R), mine dump (NP444R), quartz vein (NP443R), and brecciated and iron-stained zone in carbonates (NP455R, NP440R, NP441R, NP442R). We analyzed 103 stream-sediment samples, 103 heavy-mineral-concentrate samples, and 9 rock samples, for a sampling density of about 1 sample per 1.4 mi² for the stream sediment and heavy-mineral concentrate. The drainage basins ranged from approximately .5 mi² to 3 mi² in area.

We collected samples at 78 sites (Plate 1) in the Resting Spring WSA. At nearly all of those sites, we collected both a stream-sediment sample and a heavy-mineral concentrate. One composite grab sample of rocks from a mine dump was also collected (RS450R). We analyzed 77 stream-sediment samples, 77 heavy-mineral-concentrate samples, and one rock sample, for a sampling density of about 1 sample per 1.5 mi² for the stream sediment and heavy-mineral concentrate. The drainage basins ranged from approximately 0.5 mi² to 3 mi² in area.

Stream-sediment samples

Analyses of the stream-sediment samples represent the chemistry of the rock material eroded from the drainage basin upstream from each sample site. Such information is useful in identifying those basins which contain concentrations of elements that may be related to mineral deposits.

The stream-sediment samples consisted of active alluvium collected primarily from first-order (unbranched) and second-order (below the junction of two first-order) streams as shown on USGS topographic maps (scale = 1:62,500). Each sample was composited from several localities within an area that may extend as much as 50 ft (15 m) from the site plotted on the map.

Heavy-mineral-concentrate samples

We panned heavy-mineral-concentrate samples from the same active alluvium as the stream-sediment samples. Each bulk sample was passed through a 2.0-mm (10-mesh) screen to remove the coarse material. The sediment passing through the screen was panned until most of the quartz, feldspar, organic material, and clay-sized material was removed. The sample was air dried.

Rock samples

We collected rock samples from prospect pits, mine dumps, outcrops or exposures in the vicinity of the plotted site location. Samples were collected from altered or mineralized rock.

Sample Preparation

Only the stream-sediment samples required extensive preparation. Rock samples were simply crushed and then pulverized with ceramic plates to minus 0.15 mm. Water samples required no preparation beyond that done in the process of collecting them.

We sieved the stream-sediment samples at the collection site through a 80-mesh screen and the minus 80-mesh material was retained. The samples were air dried and sieved to 80 mm using stainless steel sieves. The portion of the sediment passing through the sieve was saved for analysis.

After panning the sediment, we used bromoform to separate and remove the remaining quartz and feldspar from the heavy-mineral concentrate. The heavy minerals (specific gravity >2.8) were separated into three fractions using a large electromagnet (in this case a modified Frantz Isodynamic Separator). The most magnetic material (largely magnetite) was discarded. The second fraction (largely ferromagnesian silicates and iron oxides) was saved for analysis/archival storage. The third fraction (the least magnetic material including nonmagnetic ore minerals, zircon, sphene, etc.) was divided into two splits using a Jones splitter. One split was hand ground for spectrographic analysis; the other split was saved for mineralogical analysis.

The magnetic separates discussed are the same separates that would be produced by removing the magnetite with a hand magnet and then using a Frantz Isodynamic Separator set at a slope of 15° and a tilt of 10° with a current of 0.1 ampere to remove the ilmenite, and a current of 1.0 ampere to split the remainder of the sample into magnetic and nonmagnetic fractions.

Sample Analysis

Spectrographic method

We analyzed the stream-sediment, heavy-mineral-concentrate, and rock samples for 31 elements using a semiquantitative, direct-current arc emission spectrographic method (Grimes and Marranzino, 1968). Spectrographic results were obtained by visual comparison of spectra derived from the sample against spectra obtained from standards made from pure oxides and carbonates. Standard concentrations are geometrically spaced over any given order of magnitude of concentration as follows: 100, 50, 20, 10, and so forth. Samples whose concentrations are estimated to fall between those values are assigned values of 70, 30, 15, and so forth. The precision of the analytical method is approximately plus or minus one reporting unit at the 83 percent confidence level and plus or minus two reporting units at the 96 percent confidence level (Motooka and Grimes, 1976). Values determined for the major elements (iron, magnesium, calcium, and titanium) are given in weight percent; all others are given in parts per million (micrograms/gram) (table 1).

Chemical methods

Other methods of analysis used on samples from the Nopah Mountain Wilderness and Resting Spring WSA's are summarized in table 2.

Analytical results for stream-sediments are listed in table 3.

ROCK ANALYSIS STORAGE SYSTEM

Upon completion of all analytical work, the analytical results were entered into a computer-based file called RASS (Rock Analysis Storage System). This RASS file contains both descriptive geological information and analytical data. Any or all of this information may be retrieved and converted to a standard form (STATPAC) for computerized statistical analysis or publication (VanTrump and Miesch, 1976).

| | Li | AA | 5 | S. Sherlock | Meier, 1980 |
| | U | Fluorometric | .1 | A. Meier | Centanni and others, 1956 |

¹The determination limit is dependent upon sample weight. Given limits imply use of sample weight required by method. Higher limits of determination result from using less than required sample weight.
